Pooling of Capacity

5

A long line for a shorter wait at the supermarket. **NYT**

What conclusion can be drawn from data?

Pooling of Capacity: Benefits

A thought experiment

6

10 separate queues

For each queue:

arrival rate = 1 / min,

service rate = 2 / min,

resources = 1

\Rightarrow *wait time* = 0.5 min

Pooling of Capacity: Benefits

A thought experiment

10 separate queues

For each queue:

arrival rate = 1 / min,

service rate = 2 / min,

resources = 1

⇒ wait time = 0.5 min

Pooled queue

arrival rate = 10 / min,

service rate = 2 / min,

resources = 10

⇒ wait time = _____

Sources of Pooling benefits are:

More effective resource utilization

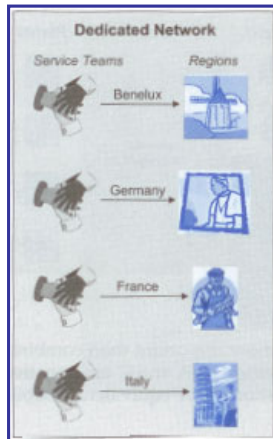

Reduction in arrival variability

What are the costs of implementing pooling?

Pooling's cost: cross-functional training

9

No pooling has long waits.

Full pooling will reduce waits but requires multi-lingual operators (high cost).

"Some" pooling gets most of the benefit at low cost. This is called **Chained Pooling**.

Practice: Pool or not?

Recall earlier question:

There is another branch of the firm that is double the size (twice the arrival rate, double resources). Should we pool?

Enter Inputs here:		
Arrival rate=		2.4
Capacity of one resource (service rate)=		3
Number of resources=		1
	Utilization=	0.8
Coefficient of variation of arrivals C_a =		1
Coefficient of variation of service C_s =		1
Read Outputs here:		
Waiting Time=	1.3333333	
Service Time=	0.3333333	
Total lead time=	1.6666667	
Number in waiting line=	3.2	
Number in system=	4	

10

What if the need for cross-functional work across two branches increases average service time by 10% (or 12%)?

Practice: Pool or not? (continuing from earlier setup)

11

There is another branch of the firm that is double the size (twice the arrival rate, double resources). Should we pool?

Bigger branch current wait:

Change arrival rate to 4.8 and number of resources to 2.

Wait = 0.6030 hr

Average wait = $(1/3) * 1.3333 + (2/3) * (0.6030) = 0.8464$ hr

After Pooling:

Change arrival rate to 7.2 and number of resources to 3.

Wait = 0.3694 hr → Pooling benefits avg. wait.

What if the need for cross-functional work across two branches increases average service time by 10% (or 12%)?

After Pooling:

Change arrival rate to 7.2 and number of resources to 3.

Change service time to $20 * 1.1 = 22$ min; service rate = $60/22$ per hr

Wait = 0.8062 hr → Pooling is good at 10% increase

OR 12% gives service time 22.4 min and wait 0.9789 hr

→ Pooling is not good at 12% increase

Key points and takeaways

12

- Capacity-Wait graph shows the impact of changing capacity on wait times and how this changes with variability. The exponential nature of the graph shows that little changes in capacity or variability can have huge impact on wait times.
- Given a target wait time, the graph and the spreadsheet model can be used to make capacity decisions.
- If a “cost of waiting” can be estimated, we can make capacity decisions by considering the trade-off between the cost of waiting and the cost of providing capacity.
- Pronto pizza problem provides an example of the above trade-off and a capacity decision in a setting with multiple stations.
- “Pooling” means that if there are different types of flow-units, a combined capacity can deliver smaller waiting times (grocery line).

Examples: Grocery line capacity management technologies

Category, sum of Number of Records and sum of cost to process invoices. Color shows sum of Number of Records. Size shows sum of Number of Records. The marks are labeled by Category, sum of Number of Records and sum of cost to process invoices. The view is filtered on Category, which excludes Null and UNCLEAN.

Application: Baria

Why this case?

- A growing business sector
- Contemporary project-type business context
- An opportunity to show how our ideas are applicable in contexts beyond mfg., retail, etc.

Step-by-step approach for capacity decisions and improvements

Identify Flow
 Balance Capacity
 Mitigate Variability
 Configure for Variety
 Qualitative ideas + Quantitative evaluation

Baria: Identify Flow & Metrics

17

Interpret the flow

Flow-unit: Sales support requests, 4 sectors, 4 types
Four stations: data engineering, data analysis
proposal support (sector-specific), pricing
Arrival rate, service rates, number of resources are given
Ca and Cs can be estimated

Performance Measure: Time

Turnaround time
Do delays influence business?

Baria: Compute Turnaround Time

18

To compute turnaround time:

Focus on a busy quarter.

Start with a total combined unit count across sectors and types and use this to compute arrival rate at data engineering, data analysis and pricing.

Separate out total arrival rate into sector arrival rates at the proposal support station.

Service time of the combined unit at each station is the weighted average service time where weights reflect product-mix for that quarter.

Ca can be derived if data is available, Ca=1 is a very reasonable assumption.

To estimate Cs, we need a measure of the standard deviation of the combined unit.

Baria Capacity Decisions

19

Ideas for Improvements? Pros and Cons.

Baria Capacity Decisions

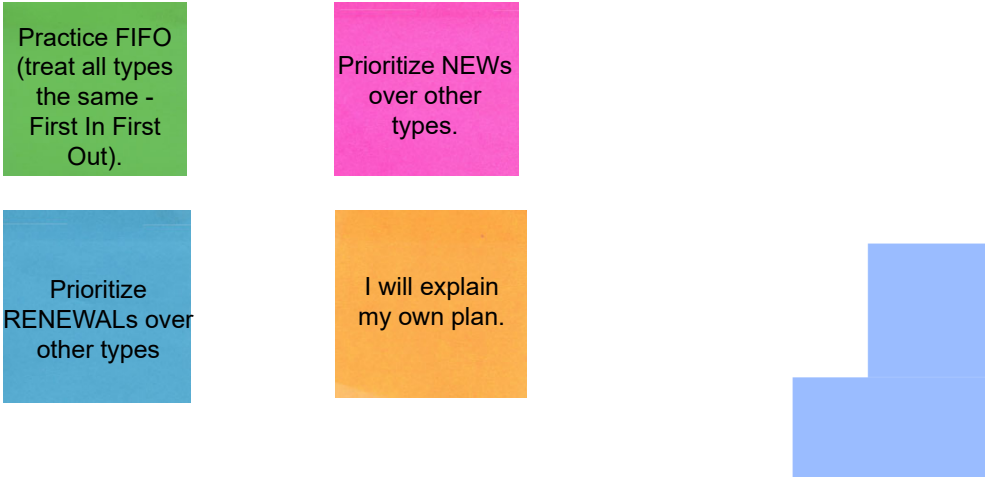

20

Cross-training can facilitate reallocation of resources to get closer to a Balanced flow. It can also allow for pooling resources across sectors. Can pooling work well in a real context?

Priority Policy

21

Baria should....

Baria Priority Decision

22

In addition to sectors, flow-units are also different from each other based on their types: New Sale, Renewal, Expansion, Pilot. The resource capacity is already pooled on this dimension. An improvement idea may be to keep the capacity pooled but deliver differentiated service by prioritizing based in types. In order to decide which type gets priority, we should think about exactly how these types are different from each other.

New					
Renewal					

Key Points: Baria

23

Identify flow:

Application of capacity analysis in a contemporary setting. Recognize predictable variability across quarters; unpredictable variability inside quarters.

Capacity decisions and improvements:

Bottleneck & Balance: Determine resources to add when and where.

Cross-train to make it possible to shift resources and balance the flow.

Mitigate variability: Practice use of spreadsheet tool to estimate impact of capacity decisions on wait times. Pooling implementation issues.

Identify sources of variability and reduce.

Configure capacity for variety:

Rank flow-unit-types based on different factors and decide which one to prioritize.

A Moment of Reflection

24

How do you prioritize orders in your workflow?

6. Make it Lean
7. Collaborate across Flow

Impact of variety on flow metrics

Variety → Variability
Slow on Learning Curve
Planning Complexity → Higher Cost
Diseconomies of Scale → Slower
Lower Quality

In other words,

Lower variety → Higher Volumes → Repetition → Cheaper
Better
Faster

But, variety is needed:
Customers want personalization
Resources dislike monotonous work

Variety: How are flow-units different?

27

Different Waiting costs. Different revenue potentials. Different service times.
Different service time variabilities. Different arrival variabilities.

How do we respond to variety in flow?

Demand Side Strategies

Admission Policies

Pricing

Batching

Supply Side Strategies

Reduce Switching Costs

Flexible Resources

Configure Capacity: Pool, Prioritize, Split

Simple priority rules

28

SPT: Shortest processing time first rule minimizes total wait.

c-mu rule: Give priority to the class with the highest value of (cost of waiting divided by service time)

In dynamic priority, the class that gets priority can change over time.

On Hold for 45 Minutes? It Might Be Your Secret Customer Score.

Retailers, wireless carriers and others crunch data to determine what shoppers are worth for the long term—and how well to treat them
WSJ 11/1/2018

In the model, the scores ranged from \$8.52 to \$203.93.

Not Worth the Time

Company will refrain from marketing to such customers and won't be in a hurry to answer their messages.

Score: \$11.39

- Single man, 22
- High-school diploma
- Lives in rural area
- Shops rarely, mostly on weekdays
- Usually buys at deep discounts
- Returns merchandise excessively

Middle of the Pack

Company will send an occasional discount.

Score: \$52.92

- Single woman, 31
- Bachelor's degree
- Lives in suburbs
- Shops a fair amount
- Browses for discounts but often exceeds budget
- Never returns merchandise

Preferred Customer

Company will invite such customers to VIP events and ensure their complaints get answered first.

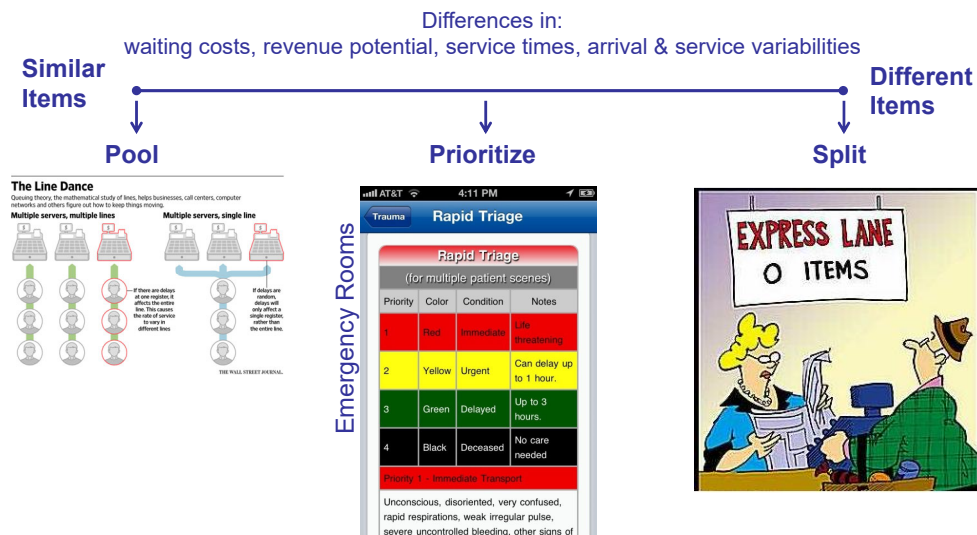

Score: \$176.14

- Married woman, 41
- Graduate degree
- Lives in big city
- Shops regularly, mostly on weekends
- Usually pays full price and rarely returns items
- Buys and browses best-quality items

MONEYBOX

Online Ordering Is Ruining Lunch for the Rest of Us

BY HENRY GRABAR OCT 04, 2021 • 12:38 PM

Foolish and increasingly uncommon behavior. Greg Gersen/Getty Images

The road to lunch is splitting into two lanes, and one of them is moving faster than the other. At Shake Shack, for example, digital sales now represent 47 percent of all orders.

Ordering on the phone is even more popular at Chipotle. In the first quarter of this year, "digital orders" grew 133 percent over the prior three months and accounted for more than half of all sales at the chain. In the spring, even as COVID restrictions eased, the number of digital sales grew another 10.5 percent to nearly a billion dollars in digital burritos. That's almost three times as many digital sales as the company did in the first quarter of 2020, before the pandemic.

Half the restaurant's digital orders come from "order-ahead transactions," many of which Most of those are placed less than 20 minutes in advance, Chipotle vice president of digital strategy and product Nicole West told me. Nearly all restaurants now have a second, hidden assembly line for digital orders, and Chipotle recently opened its first store, in Highland Falls, New York, that does not accept orders in person at all.

Examples

32

Examples

Key points & takeaways

Flow-units can differ from each other on two major dimensions:
Cost of waiting and Service burden

If flow-units are not very different from each other on the above dimensions, pooling with FCFS strategy is usually preferable over split capacity. There may be a one-time cost for cross-functional resource training but the benefits occur continuously.

If flow-units differ only on Service time dimension, SPT rule (shortest Processing or service time first) rule minimizes total wait.

If flow-units are also different on cost-of-waiting dimension, c-mu rule is shown to be effective.

c-mu rule: Give priority to the class with the highest value of
(cost of waiting divided by service time)

If flow-unit types differ significantly in above dimensions, a split-capacity strategy is practical.

In practice, cost-of-waiting may not be easy to measure. In addition, there may be other business differences between flow-units. Rank flow-units on each dimension and propose an overall ranking for determining which flow-unit gets priority.

Operations & Business Process Management

Prof. Apurva Jain
MSIS 503

Classifying flow-units based on their characteristics and prioritizing based on a simple index is effective in practice. If similar, pool and if too different, split the capacity.
